AppKit: Using the DS1620 Digital Thermometer/Thermostat

This AppKit shows how to use the Dallas Semiconductor DS1620 Digital Thermometer/ Thermostat chip with PIC microcontrollers and the Parallax BASIC Stamp[®] single-board computer.

Description

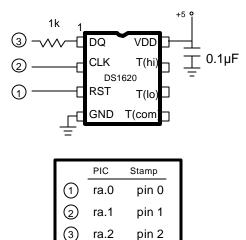

The DS1620 is a complete digital thermometer on a chip, capable of replacing the normal combination of temperature sensor and analog-to-digital converter in most applications. It can measure temperature in units of 0.5° Centigrade (C) from –55° C to +125° C. [In Fahrenheit (°F), units of 0.9° F and a range of –67° F to +257° F.] Temperature measurements are expressed as nine-bit, two's complement numbers. The DS1620 communicates with a microcontroller such as the PIC or Stamp through a three-wire serial connection.

The DS1620 can also operate as a standalone thermostat. A temporary connection to a controller establishes the mode of operation and high/low-temperature setpoints. Thereafter, the chip independently controls three outputs: T(high), which goes active at temperatures above the high-temperature setpoint; T(low), active at temperatures below the low setpoint; and T(com), which goes active at temperatures above the high setpoint, and stays active until the temperature drops below the low setpoint.

Hardware interface

The DS1620 interfaces with controllers through a three-wire connection, consisting of a data input/output line (DQ), a synchronizing clock line (CLK) and a reset/select line (RST).

The figure shows how to connect the DS1620 to the PIC or Stamp for the demo programs. Do not omit the bypass capacitor—not even if you feel that your power supply is solid and well-filtered. Locate that cap as close as practical to the supply leads of the DS1620. Although the 1k resistor is not strictly necessary as long as the firmware is functioning correctly, it's best to leave it in. In the event that both the controller (PIC or Stamp) and the DS1620 try to drive the data line at the same time, the resistor limits the amount of current that can flow between them to a safe value.

Software interface

From a software standpoint, using the DS1620 boils down to this:

- (1) Activate RST by taking it high.
- (2) Send an instruction (protocol) to the DS1620 telling it what you want to do.
- (3) If you are reading data, shift it into the controller (PIC or Stamp).
- (4) If you are writing data, shift it out to the DS1620.
- (5) Deactivate RST by taking it low.

The program listings and data sheets show these processes in detail.

Tips for using the DS1620

- Data written to the DS1620 configuration or temperature-setpoint registers is stored in EEPROM. It takes as long as 50 milliseconds (ms) to complete the write. Be sure to program a delay of at least this length before sending further commands to the DS1620.
- The fastest the DS1620 can generate new temperature data is once per second. It does no good to read it at shorter intervals—you'll simply read the value of the previous temperature measurement.
- The DS1620's thermostat outputs can source only 1 mA and sink only 4 mA. You'll need a Darlington-transistor or logic-level MOSFET switch to turn on a decent-sized load.

PIC Program Listing

; Program: DS1620.SRC (interface with DS1620 digital thermometer)

; This program presents PIC assembly language subroutines for communicating

; with the DS1620 digital thermometer chip. It also provides tables of

; predefined constants called "protocols" that control the chip's various

; operating modes. This demo configures the DS1620 as a temperature

; sensor slaved to a controller ("CPU" mode) and requests that it perform

; continuous temperature measurements. The '1620 may also be configured as

; a standalone thermostat with setpoint stored in nonvolatile EEPROM.

PIC Program Listing (cont.)

; ====================================			
device	pic16c54,xt_osc,wdt_off,protect_off		
reset	start		
org	0		

; Main program start.

; To demonstrate communication with the DS1620, we're going to set its

; configuration register to CPU mode and continuous conversion, then

; continuously read the temperature. The results of the temperature readings

; will be written to port RB (eight Isbs) and ra.3 (msb). You can view the readings

; (in binary) by connecting LEDs to these pins through 220-ohm resistors.

start	mov	ra,#0	; Clear ports
	mov	rb,#0	
	mov	!ra,#DQout	; Port ra: all outputs.
	mov	!rb,#0	; Output for eight Isbs of temp reading.
	clrb	clk9	; Clear the ninth-bit clock flag.
	setb	CLK	; Set the clock to prepare for comms.
	mov	DSdata,#Wconfig	; Put write-config protocol into output byte.
	call	Shout	; Send it to the 1620.
	mov	DSdata,#CPU	; Configure as thermometer
	OR	DSdata,#Cont	;continuous conversion.
	call	Shout	; Send that to the 1620.
	clrb	RST	; Deactivate the 1620.
	call	delay	; Wait for EEPROM programming cycle.
	mov	DSdata,#StartC	; Start conversions by sending
	call	Shout	; the start protocol to the 1620.
	clrb	RST	; Deactivate the 1620.
:loop	call	delay	; Short *delay between reads.
	mov	DSdata,#Rtemp	; Send read-temperature protocol.
	call	Shout	
	call	Shin	; Get the temperature data.
	movb	ra.3,sign	; Write ninth bit to ra.3.
	mov	rb,DSdata	; Write lower eight bits to port rb.
	jmp	:loop	; Repeat forever.
	J L.	1-	,

; * Note that the DS1620 can only perform one conversion per second.

; With a 4-MHz clock, this demo routine reads it about five times a

; second. This doesn't do any harm, since the DS1620 provides the

; old reading until a new one is available, but it doesn't do any

; good either! In an actual application, you'll want to read the '1620

; only as often as appropriate.

PIC Program Listing (cont.)

; ======= DS1620 Communication Routines ==========

; >> Note that callable subroutines should normally come _before_ the

; body of the program (or be placed there in program memory using "org"

; directives) to ensure that call destinations fall in the lower 256

; addresses of a program-memory page. In example programs like this

; we frequently break this rule since it makes the program more readable.

; Shout shifts out the 8 bits of DSdata and, optionally, the ninth bit

; stored in sign. Eight-bit transfers are required for sending instructions

; (called protocols) to the DS1620. Nine-bit transfers are required for

; storing temperature data to the 1620's thermostat registers. In either

; case, the internal loop executes 9 times. For an eight-bit transfer

; (set up by storing a 0 to clk9) the last clock pulse is skipped. Always

; looping 9 times has the benefit of leaving the value of DSdata unaltered

; after a call to Shout. The bits are rotated back into their original

; positions.

; >> Note: Since all communications with the DS1620 begin with the controller

; sending a protocol, Shout contains the "setb RST" command required to

; activate the DS1620. Since communications can end with either an output

; (Shout) or an input (Shin), Shout does _not_ deactivate the DS1620. Make

; sure to take care of this detail in your code that uses this routine.

Shout

	mov	!ra,#DQout	; Set to output.
	mov	bits,#9	; Set up for 8- or 9-bit transfer.
	movb	c,sign	; Put bit8 (sign bit) into carry.
:begin	setb	RST	; Activate the 1620.
:loop	rr	DSdata	; Rotate bit0 of DSdata into carry.
	clrb	CLK	; Set up for clock pulse
	movb	DQ,c	; Move carry bit to input of 1620.
	mov	w,bits	; Pulse the clock line for each of
	snz		; first 8 bits. On the ninth bit,
	snb	clk9	; pulse the clock only if $clk9 = 1$.
	setb	CLK	; Finish the pulse if conditions are met.
	djnz	bits,:loop	; Loop 9 times.
	ret		

PIC Program Listing (cont.)

; Shin shifts in data from the 1620. If the data to be received is

; a 9-bit temperature, the lower 8 bits are in DSdata and the 9th (sign)

; bit is in the carry bit. If the data is a configuration byte, ignore the

; extra bit in carry.

; >> Note: When a program receives input from the DS1620, it is always the

; end of the communication, so Shin incorporates the command "clrb RST"

; to deactivate the DS1620.

Shin

	mov	!ra,#DQin	; Set DQ to input.
	mov	bits,#9	; Nine-bit transfer.
	clc		; Clear carry bit.
:loop	rr	DSdata	; Move carry into bit7, shift bits right.
	clrb	CLK	; Clock in the bit on falling edge.
	movb	c,DQ	; Get the bit
	setb	CLK	; Finish the clock pulse.
	djnz	bits,:loop	; Loop 9 times.
	clrb	RST	; Deactivate the 1620.
	ret		

; General-purpose delay routine (200+ ms at 4 MHz).

; Not required by DS1620 routines per se, but used to wait for EEPROM

; programming cycles to finish (50 ms max) and to wait an interval

; between temperature readings.

return
```

' Calculate degrees below 0.

BASIC Stamp I (BS1-IC) and BASIC Stamp Ver. D Program Listing: Thermostat

'Program: DS_STAT.BS1

' This program interfaces the DS1620 Digital Thermometer to the

'BASIC Stamp to configure it for thermostat operation. A PC

' running terminal software, should be connected to the Stamp

' with data out to pin 4 (through a 22k resistor) and data in

' to pin 3:

1	Function	DB25 Pin	DB	89 Pin	Stamp Pin
1	GND	7	5	GN	D
1	Transmit	2	3	4	
1	Receive	3	2	3	

' Hardware handshaking must be disabled in the terminal software.

' Communication format is 2400 baud, no parity, 8 data bits,

' 1 stop bit. The Stamp prompts the user for the high and low

' temperature setpoints, then copies these to the registers of the

'DS1620. The setpoints _must_ be preceded by the appropriate sign

' (+ or -). The program does not assume that "78" means "+78."

' Once the DS1620 is programmed, the circuit should be turned

' off, and the DS1620 removed for installation in its standalone

' thermostat application.

BASIC Stamp II (BS2-IC) Program Listing: Thermometer

' Program: DS1620.BS2 (interface DS1620 digital thermometer to BS2)

This program interfaces the DS1620 Digital Thermometer to
the BS2. Input and output routines can be combined to set
the '1620 for thermometer or thermostat operation, read
or write nonvolatile temperature setpoints and configuration
data. In addition to using the BS2's new Shiftin and Shiftout
instructions to communicate with the 1620, this program uses
new math and display operators that work with signed integers.
This makes it relatively easy to convert between degrees C and
F and to display both positive and negative temperature
it's necessary to "extend the sign bits." All this means is
setting all of the bits to the left of actual value to 1s.

Also note the use of the new */ (pronounced 'star-slash')
' operator. This works like multiplying by an integer (0-255)
' and a fraction (in units of 1/256). For example, to multiply
' 17 by Pi (approx 3.1416) would be written "17 */ \$0324."
' The second value is written in hex to emphasize that it's being
' split into bytes: \$03 is the integer and \$24/\$100 is the fraction.
' In the C-to-F conversion below, we multiply the C value by 1.8
' with "*/ \$01CC" since \$CC/\$FF (204/256) = 0.8.

PRELIMINARY

DALLAS SEMICONDUCTOR

Digital Thermometer and Thermostat

FEATURES

- · Requires no external components
- Measures temperatures from -55°C to +125°C in 0.5°C increments. Fahrenheit equivalent is -67°F to 257°F in 0.9°F increments
- Temperature is read as a 9-bit value
- Converts temperature to digital word in 1 second
- Thermostatic settings are user-definable and nonvolatile
- Data is read from/written via a 3-wire serial interface (CLK, DQ, RST)
- Applications include thermostatic controls, industrial systems, consumer products, thermometers, or any thermally sensitive system

The DS1620 Digital Thermometer and Thermostat pro-

vides 9-bit temperature readings which indicate the

temperature of the device. With three thermal alarm out-

puts, the DS1620 can also act as a thermostat. T_{HIGH} is

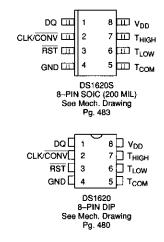

driven high if the DS1620's temperature is greater than or equal to a user-defined temperature TH. T_{LOW} is

driven high if the DS1620's temperature is less than or equal to a user-defined temperature TL. T_{COM} is driven

8-pin DIP or SOIC package

DESCRIPTION

high when the temperature exceeds TH and stays high until the temperature falls below that of TL.

User-defined temperature settings are stored in nonvolatile memory, so parts can be programmed prior to insertion in a system, as well as used in standalone applications without a CPU. Temperature settings and temperature readings are all communicated to/from the DS1620 over a simple 3-wire interface.

OPERATION-READING TEMPERATURE

The DS1620 measures temperatures through the use of an onboard, proprietary temperature measurement technique. The temperature reading is provided in a 9-bit, two's complement format. Table 1 describes the exact relationship of output data to measured temperature. The data is transmitted serially through the 3-wire serial interface, LSB first. The DS1620 can measure temperature over the range of -55° C to $+125^{\circ}$ C in 0.5°C increments. For Fahrenheit usage, a lookup table or conversion factor must be used. Since data is transmitted over the 3-wire bus LSB first, temperature data can be written to/read from the DS1620 as either a 9-bit word (taking RST low after the 9th (MSB) bit), or as two transfers of 8-bit words, with the most significant 7 bits being ignored or set to zero, as illustrated in Table 1. After the MSB, the DS1620 will output 0's.

Note that temperature is represented in the DS1620 in terms of a $^{1}/_{2}$ °C LSB, yielding the following 9-bit format:

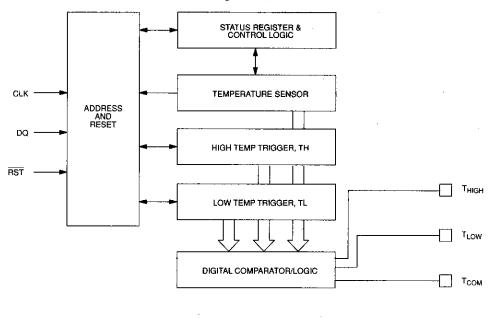

TEMPERATURE/DATA RELATIONSHIPS Table 1

ТЕМР	DIGITAL OUTPUT (Binary)	DIGITAL OUTPUT (Hex)

PIN	SYMBOL	DESCRIPTION
1	DQ	Data Input/Output pin for 3-wire communication port.
2	CLK/CONV	Clock Input pin for 3-wire communication port. When the DS1620 is used in a standalone application with no 3-wire port, this pin can be used as a convert pin. Temperature conversion will begin on the falling edge of CONV.
3	RST	Reset input pln for 3-wire communication port.
4	GND	Ground pin.
5	Т _{СОМ}	High/Low Combination Trigger. Goes high when temperature exceeds TH; will reset to low when temperature falls below TL.
6	TLOW	Low Temperature Trigger. Goes high when temperature falls below TL.
7	T _{HIGH}	High Temperature Trigger. Goes high when temperature exceeds TH.
8	V _{DD}	Supply Voltage. 5V input power pin.

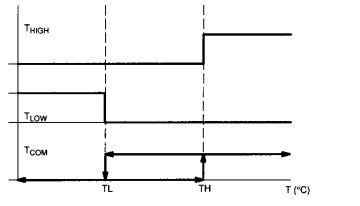

DETAILED PIN DESCRIPTION Table 2

OPERATION-THERMOSTAT CONTROLS

Three thermally triggered outputs, T_{HIGH} , T_{LOW} , and T_{COM} , are provided to allow the DS1620 to be used as a thermostat, as shown in Figure 2. When the DS1620's temperature meets or exceeds the value stored in the high temperature trip register, the output T_{HIGH} becomes active (high) and remains active until the DS1620's measured temperature becomes less than the stored value in the high temperature register, TH. The T_{HIGH} output can be used to indicate that a high temperature tolerance boundary has been met or exceeded, or as part of a closed loop system can be used to activate it when the system temperature returns to tolerance.

The T_{LOW} output functions similarly to the T_{HIGH} output. When the DS1620's measured temperature equals or

THERMOSTAT OUTPUT OPERATION Figure 2

sales / technical support (916) 624-8333 • fax (916) 624-8003 pictech@parallainc.com • stamptech@parallaxinc.com

fails below the value stored in the low temperature register, the T_{LOW} output becomes active. T_{LOW} remains active until the DS1620's temperature becomes greater than the value stored in the low temperature register, TL. The T_{LOW} output can be used to indicate that a low temperature tolerance boundary has been met or exceeded, or as part of a closed loop system, can be used to activate a heating system and to deactivate it when the system temperature returns to tolerance.

The T_{COM} output goes high when the measured temperature meets or exceeds TH, and will stay high until the temperature equals or falls below TL. In this way, any amount of hysteresis can be obtained.

OPERATION AND CONTROL

The DS1620 must have temperature settings resident in the TH and TL registers for thermostatic operation. A configuration/status register is also used to determine the method of operation that the DS1620 will use in a particular application, as well as indicating the status of the temperature conversion operation. The configuration register is defined as follows:

CONFIGURATION/STATUS REGISTER	CONFIGU	IRATION/STATU	IS REGISTER
-------------------------------	---------	---------------	-------------

			_				
DONE	THF	TLF	х	×	x	CPU	ISHOT

where

- X = Don't Care
- DONE = Conversion Done bit. 1=conversion complete, 0=conversion in progress.
- THF = Temperature High Flag. This bit will be set to 1 when the temperature is greater than or equal to the value of TH. It will remain 1 until reset by writing 0 into this location or by removing power from the device. This feature provides a method of determining if the DS1620 has ever been subjected to temperatures above TH while power has been applied.

TLF = Temperature Low Flag. This bit will be set to 1 when the temperature is less than or equal to the value of TL. It will remain 1 until reset by writing 0 into this location or by removing power from the device. This feature provides a method of determining if the DS1620 has ever been subjected to temperatures below TL while power has been applied.

- CPU = CPU use bit. If CPU=0, the CLK/CONV pin acts as a conversion start control, when RST is low. If CPU is 1, the DS1620 will be used with a CPU communicating to it over the 3-wire port, and the operation of the CLK/CONV pin is as a normal clock in concert with DQ and RST.
- 1SHOT = One-Shot Mode. If 1SHOT is 1, the DS1620 will perform one temperature conversion upon reception of the Start

Convert T protocol. If 1SHOT is 0, the DS1620 will continuously perform temperature conversion.

For typical thermostat operation, the DS1620 will operate in continuous mode. However, for applications where only one reading is needed at certain times, and to conserve power, the one-shot mode may be used. Note that the thermostat outputs (T_{HIGH} , T_{LOW} , T_{COM}) will remain in the state they were in after the last valid temperature conversion cycle when operating in one-shot mode.

OPERATION IN STANDALONE MODE

In applications where the DS1620 is used as a simple thermostat, no CPU is required. Since the temperature limits are nonvolatile, the DS1620 can be programmed prior to insertion in the system. In order to facilitate operation without a CPU, the CLK/CONV pin (pin 3) can be used to initiate conversions. Note that the CPU bit must be set to 0 in the configuration register to use this mode of operation.

To use the CLK/CONV pin to initiate conversions, RST must be low and CLK/CONV must be high. If CLK/ CONV is driven low and then brought high in less than 10 ms, one temperature conversion will be performed and then the DS1620 will return to an idle state. If CLK/ CONV is driven low and remains low, continuous conversions will take place until CLK/CONV is brought high again. With the CPU bit set to 0, the CLK/CONV will override the 1-shot bit if it is equal to 1. This means that even if the part is set for one-shot mode, driving CLK/ CONV low will initiate conversions.

3-WIRE COMMUNICATIONS

The 3-wire bus is comprised of three signals. These are the \overrightarrow{RST} (reset) signal, the CLK (clock) signal, and the DQ (data) signal. All data transfers are initiated by driving the \overrightarrow{RST} input high. Driving the \overrightarrow{RST} input low terminates communication. (See Figures 3 and 4.) A clock cycle is a sequence of a falling edge followed by a rising edge. For data inputs, the data must be valid during the rising edge of a clock cycle. Data bits are output on the falling edge of the clock, and remain valid through the rising edge.

030794 4/9

sales / technical support (916) 624-8333 • fax (916) 624-8003 pictech@parallainc.com • stamptech@parallaxinc.com

435

When reading data from the DS1620, the DQ pin goes to a high impedance state while the clock is high. Taking RST low will terminate any communication and cause the DQ pin to go to a high impedance state.

Data over the 3-wire interface is communicated LSB first. The command set for the 3-wire interface as shown in Table 3 is as follows; only these protocols should be written to the DS1620, as writing other protocols to the device may result in permanent damage to the part.

Read Temperature [AAh]

This command reads the contents of the register which contains the last temperature conversion result. The next nine clock cycles will output the contents of this register.

Write TH [01h]

This command writes to the TH (HIGH TEMPERA-TURE) register. After issuing this command, the next nine clock cycles clock in the 9-bit temperature limit which will set the threshold for operation of the T_{HIGH} output.

Write TL [02h]

This command writes to the TL (LOW TEMPERA-TURE) register. After issuing this command, the next nine clock cycles clock in the 9-bit temperature limit which will set the threshold for operation of the T_{LOW} output.

Read TH [A1h]

This command reads the value of the TH (HIGH TEM-PERATURE) register. After issuing this command, the next nine clock cycles clock out the 9-bit temperature limit which sets the threshold for operation of the $T_{\mbox{HIGH}}$ output.

Read TL [A2h]

This command reads the value of the TL (LOW TEM-PERATURE) register. After issuing this command, the next nine clock cycles clock out the 9-bit temperature limit which sets the threshold for operation of the T_{LOW} output.

Start Convert T [EEh]

This command begins a temperature conversion. No further data is required. In one-shot mode, the temperature conversion will be performed and then the DS1620 will remain idle. In continuous mode, this command will initiate continuous conversions.

Stop Convert T [22h]

This command stops temperature conversion. No further data is required. This command may be used to halt a DS1620 in continuous conversion mode. After issuing this command, the current temperature measurement will be completed, and then the DS1620 will remain idle until a Start Convert T is issued to resume continuous operation.

Write Config [0Ch]

This command writes to the configuration register. After issuing this command, the next eight clock cycles clock in the value of the configuration register.

Read Config [ACh]

436

This command reads the value in the configuration register. After issuing this command, the next eight clock cycles output the value of the configuration register.
